

A HOLDING MECHANISM FOR HOLDING OF FABRICS

The invention relates to a holding mechanism for holding of pieces of fabric (22), comprising a base holder (11), which can be fastened on a wall (16), and a rocker arm (12), which is arranged pivotally about an axis of rotation (13) on the base holder (11), with an upper and a lower leg (20, 21), whereby a piece of fabric (22), which is to be held, can be clamped between a first clamping surface (26) existing on the lower leg (20) of the rocker lever (12) and a second clamping surface (27). It is suggested that the clamping surfaces (26, 27) define an upwardly open receiving channel (19) for the piece of fabric (22), which is to be held, and that at least one bearing surface (23) for placing of the piece of fabric (22) is provided on the upper leg (21) of the rocker arm (12), so that a piece of fabric (22), which has been moved into the receiving channel (19), is placed over the bearing surface (23) and lies on the bearing surface (23), operates the rocker arm (12) with its gravity, whereby the first deviates toward the second clamping surface (26, 27) and a section of the piece of fabric (22), which section is between the clamping surfaces (26, 27), is clamped.
